Thermoelectric effect

We have discussed the current that flows when a voltage is applied between the two contacts,

$$I = \frac{e}{\hbar} \frac{\gamma_D \gamma_S}{\gamma_S + \gamma_D} \int D(E - \mu) [f_S(E) - f_D(E)] dE \quad (1)$$

It does not matter whether the equilibrium Fermi energy μ lies on the lower end or the upper end of the DOS.

- Visualize this situation, by assuming very small bias voltage V . Use $\gamma_D = \gamma_S = 0.005$ eV and create a python module named tools.py to contain the Lorentzian.

We can produce a current also without applying a bias voltage if we simply heat up one contact relative to the other, such that $T_S > T_D$.

- Plot Fermi functions for $T = 300, 310$ K ($k_B = 8.6174 \times 10^{-5}$ eV/K) and their difference. Add the Fermi function to tools.py.
- Plot the corresponding current as a function of -0.25 eV $< \mu < 0.25$ eV. Use another python module constants.py to store the necessary constants $k_B, e = 1.602 \times 10^{-19}$ As, $\hbar = 1.055 \times 10^{-34}$ Js, $1\text{eV} = 1.602 \times 10^{-19}$ J.
